#### 1. Taylor's theorem

• Taylor's theorem shows how smooth functions can be locally approximated by low-order (e.g., linear or quadratic) functions.

定理 12.3.1(Taylor 公式) 设 f(x,y) 在点 $(x_0,y_0)$ 的邻域  $U = O((x_0,y_0),r)$ 上具有k+1阶连续偏导数,那么对于 U内每一点 $(x_0 + \Delta x, y_0 + \Delta y)$ 都成立

#### Theorem 1

Given a continuously differentiable function  $f : \mathbb{R}^n \to \mathbb{R}$ , we have

$$f(\mathbf{x} + \mathbf{p}) = f(\mathbf{x}) + \nabla f(\mathbf{x} + \xi \mathbf{p})^{\top} \mathbf{p}, \text{ for some } \xi \in (0, 1),$$

$$f(\mathbf{x} + \mathbf{p}) = f(\mathbf{x}) + \int_0^1 \nabla f(\mathbf{x} + t\mathbf{p})^\top \mathbf{p} dt,$$
$$f(\mathbf{x} + \mathbf{p}) = f(\mathbf{x}) + \nabla f(\mathbf{x})^\top \mathbf{p} + o(\|\mathbf{p}\|).$$

If f is twice continuously differentiable, we have for some  $\xi \in (0, 1)$ ,

$$f(\mathbf{x} + \mathbf{p}) = f(\mathbf{x}) + \nabla f(\mathbf{x})^{\top} \mathbf{p} + \frac{1}{2} \mathbf{p}^{\top} \nabla^2 f(\mathbf{x} + \xi \mathbf{p}) \mathbf{p},$$

and

$$\nabla f(\mathbf{x} + \mathbf{p}) = \nabla f(\mathbf{x}) + \int_0^1 \nabla^2 f(\mathbf{x} + t\mathbf{p})\mathbf{p}dt,$$

$$f(\mathbf{x} + \mathbf{p}) = f(\mathbf{x}) + \nabla f(\mathbf{x})^{\top} \mathbf{p} + \frac{1}{2} \mathbf{p}^{\top} \nabla^2 f(\mathbf{x}) \mathbf{p} + o(\|\mathbf{p}\|^2).$$

# 2. Global and local solutions of $\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x})$

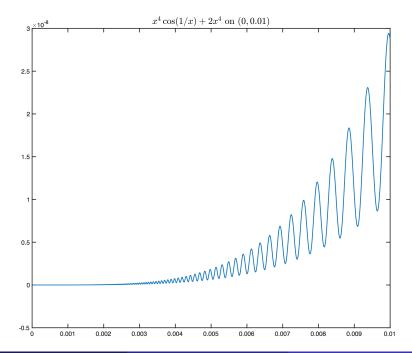

- $\mathbf{x}_{\star}$  is a *local minimizer* of f if there is a neighborhood  $\mathcal{N}$  of  $\mathbf{x}_{\star}$  such that  $f(\mathbf{x}) \geq f(\mathbf{x}_{\star})$  for all  $\mathbf{x} \in \mathcal{N}$ .
- $\mathbf{x}_{\star}$  is a strict local minimizer if it is a local minimizer on some neighborhood  $\mathcal{N}$  and in addition  $f(\mathbf{x}) > f(\mathbf{x}_{\star})$  for all  $\mathbf{x} \in \mathcal{N}$  with  $\mathbf{x} \neq \mathbf{x}_{\star}$ .
- $\mathbf{x}_{\star}$  is an *isolated local minimizer* if there is a neighborhood  $\mathcal{N}$  of  $\mathbf{x}_{\star}$  such that  $f(\mathbf{x}) \geq f(\mathbf{x}_{\star})$  for all  $\mathbf{x} \in \mathcal{N}$  and in addition,  $\mathcal{N}$  contains no local minimizers other than  $\mathbf{x}_{\star}$ .

Strict local minimizers are not always isolated: for example,

$$f(x) = x^4 \cos(1/x) + 2x^4, \ f(0) = 0.$$

All isolated local minimizers are strict.

•  $\mathbf{x}_{\star}$  is a global minimizer of f if  $f(\mathbf{x}) \geq f(\mathbf{x}_{\star})$  for all  $\mathbf{x} \in \mathbb{R}^{n}$ .

Data Analysis & Matrix Comp.

# 3. Optimality conditions for smooth functions

# Theorem 2 (First-order necessary condition)

If  $\mathbf{x}_{\star}$  is a local minimizer of f and f is continuously differentiable in an open neighborhood of  $\mathbf{x}_{\star}$ , then  $\nabla f(\mathbf{x}_{\star}) = \mathbf{0}$ .

*Proof.* Suppose for contradiction that  $\nabla f(\mathbf{x}_{\star}) \neq \mathbf{0}$ . Define the vector  $\mathbf{p} = -\nabla f(\mathbf{x}_{\star})$  and note that  $\mathbf{p}^{\top} \nabla f(\mathbf{x}_{\star}) = -\|\nabla f(\mathbf{x}_{\star})\|^2 < 0$ . Because  $\nabla f$  is continuous near  $\mathbf{x}_{\star}$ , there is a scalar T > 0 such that

$$\mathbf{p}^{\top} \nabla f(\mathbf{x}_{\star} + t\mathbf{p}) < 0, \text{ for all } t \in [0, T].$$

For any  $s \in (0, T]$ , we have by Taylor's theorem that

$$f(\mathbf{x}_{\star} + s\mathbf{p}) = f(\mathbf{x}_{\star}) + s\mathbf{p}^{\top}\nabla f(\mathbf{x}_{\star} + \xi s\mathbf{p}) \quad \text{for some} \quad \xi \in (0, 1).$$

Therefore,  $f(\mathbf{x}_{\star} + s\mathbf{p}) < f(\mathbf{x}_{\star})$  for all  $s \in (0, T]$ . We have found a direction leading away from  $\mathbf{x}_{\star}$  along which f decreases, so  $\mathbf{x}_{\star}$  is not a local minimizer, and we have a contradiction.

#### Theorem 3 (Second-order necessary conditions)

If  $\mathbf{x}_{\star}$  is a local minimizer of f and  $\nabla^2 f$  is continuous in an open neighborhood of  $\mathbf{x}_{\star}$ , then  $\nabla f(\mathbf{x}_{\star}) = \mathbf{0}$  and  $\nabla^2 f(\mathbf{x}_{\star}) \succeq \mathbf{0}$ .

**Proof.** We know from Theorem 2 that  $\nabla f(\mathbf{x}_{\star}) = \mathbf{0}$ . Assume that  $\nabla^2 f(\mathbf{x}_{\star})$  is not positive semidefinite. Then we can choose a vector  $\mathbf{p}$  such that  $\mathbf{p}^{\top} \nabla^2 f(\mathbf{x}_{\star}) \mathbf{p} < 0$ , and because  $\nabla^2 f$  is continuous near  $\mathbf{x}_{\star}$ , there is a scalar T > 0 such that

$$\mathbf{p}^{\top} \nabla^2 f(\mathbf{x}_{\star} + t\mathbf{p}) \mathbf{p} < 0, \quad \text{for all} \quad t \in [0, T].$$

By doing a Taylor series expansion around  $\mathbf{x}_{\star}$ , we have for all  $s \in (0, T]$ and some  $\xi \in (0, 1)$  that

$$f(\mathbf{x}_{\star} + s\mathbf{p}) = f(\mathbf{x}_{\star}) + s\mathbf{p}^{\top}\nabla f(\mathbf{x}_{\star}) + \frac{1}{2}s^{2}\mathbf{p}^{\top}\nabla^{2}f(\mathbf{x}_{\star} + \xi s\mathbf{p})\mathbf{p} < f(\mathbf{x}_{\star}).$$

As in Theorem 2, we have found a direction from  $\mathbf{x}_{\star}$  along which f is decreasing, and so again,  $\mathbf{x}_{\star}$  is not a local minimizer.

Data Analysis & Matrix Comp.

#### Theorem 4 (Second-order sufficient conditions)

Suppose that  $\nabla^2 f$  is continuous in an open neighborhood of  $\mathbf{x}_{\star}$  and that  $\nabla f(\mathbf{x}_{\star}) = \mathbf{0}$  and  $\nabla^2 f(\mathbf{x}_{\star}) \succ \mathbf{0}$ . Then  $\mathbf{x}_{\star}$  is a strict local minimizer of f.

*Proof.* Because the Hessian  $\nabla^2 f$  is continuous and positive definite at  $\mathbf{x}_{\star}$ , we can choose a radius r > 0 so that  $\nabla^2 f(\mathbf{x})$  remains positive definite for all  $\mathbf{x}$  in the open ball  $\mathcal{B} = \{\mathbf{z} \mid ||\mathbf{z} - \mathbf{x}_{\star}|| < r\}$ . Taking any nonzero vector  $\mathbf{p}$  with  $||\mathbf{p}|| < r$ , we have  $\mathbf{x}_{\star} + \mathbf{p} \in \mathcal{B}$  and

$$f(\mathbf{x}_{\star} + \mathbf{p}) = f(\mathbf{x}_{\star}) + \mathbf{p}^{\top} \nabla f(\mathbf{x}_{\star}) + \frac{1}{2} \mathbf{p}^{\top} \nabla^2 f(\mathbf{x}_{\star} + \xi \mathbf{p}) \mathbf{p}$$
$$= f(\mathbf{x}_{\star}) + \frac{1}{2} \mathbf{p}^{\top} \nabla^2 f(\mathbf{x}_{\star} + \xi \mathbf{p}) \mathbf{p},$$

for some  $\xi \in (0, 1)$ . Since  $\mathbf{x}_{\star} + \xi \mathbf{p} \in \mathcal{B}$ , we have

$$\mathbf{p}^{\top} \nabla^2 f(\mathbf{x}_{\star} + \xi \mathbf{p}) \mathbf{p} > 0,$$

and therefore  $f(\mathbf{x}_{\star} + \mathbf{p}) > f(\mathbf{x}_{\star})$ , giving the result.

• A point **x** is called a *stationary point* if

$$\nabla f(\mathbf{x}) = \mathbf{0}.$$

• A stationary point **x** is called a *saddle point* if there exist **u** and **v** such that

$$f(\mathbf{x} + \alpha \mathbf{u}) < f(\mathbf{x})$$
 and  $f(\mathbf{x} + \alpha \mathbf{v}) > f(\mathbf{x})$ 

for all sufficiently small  $\alpha > 0$ .

- Stationary points are not necessarily local minimizers. Stationary points can be *local maximizers* or *saddle points*.
- If ∇f(x) = 0, and ∇<sup>2</sup>f(x) has both strictly positive and strictly negative eigenvalues, then x is a saddle point.
- If ∇<sup>2</sup> f(x) is positive semidefinite or negative semidefinite, then ∇<sup>2</sup> f(x) alone is insufficient to classify x.

## 4. Line search methods

• Consider an iterative method:

$$\mathbf{x}_{k+1} = \mathbf{x}_k + t_k \mathbf{d}_k, \quad k = 0, 1, 2, \dots,$$

where  $\mathbf{d}_k$  is the *direction* and  $t_k > 0$  is the *stepsize*.

Let f: ℝ<sup>n</sup> → ℝ be a continuously differentiable function over ℝ<sup>n</sup>.
 A nonzero vector d ∈ ℝ<sup>n</sup> is called a *descent direction* of f at x if the directional derivative f'(x; d) is negative, meaning that

$$f'(\mathbf{x}, \mathbf{d}) = \nabla f(\mathbf{x})^\top \mathbf{d} < 0.$$

Lemma 5 (descent property of descent directions)

Let f be a continuously differentiable function over an open set U, and let  $\mathbf{x} \in U$ . Suppose that **d** is a descent direction of f at  $\mathbf{x}$ . Then there exists  $\varepsilon > 0$  such that

$$f(\mathbf{x} + t\mathbf{d}) < f(\mathbf{x}) \text{ for any } t \in (0, \varepsilon].$$

#### 4.1 Choices for stepsize selection rules

Assume that d<sub>k</sub> is a descent direction. Three popular choices:
(1) constant. t<sub>k</sub> = t

(2) exact line search. t<sub>k</sub> is a minimizer of f along the ray x<sub>k</sub> + td<sub>k</sub>, i.e.,

$$t_k \in \operatorname*{argmin}_{t \ge 0} f(\mathbf{x}_k + t\mathbf{d}_k)$$

(3) **backtracking**. Three parameters s > 0,  $\alpha \in (0, 1)$ ,  $\beta \in (0, 1)$ . First, set  $t_k = s$ . Then, while

$$f(\mathbf{x}_k) - f(\mathbf{x}_k + t_k \mathbf{d}_k) < -\alpha t_k \nabla f(\mathbf{x}_k)^\top \mathbf{d}_k,$$

set  $t_k \leftarrow \beta t_k$ . In other words,  $t_k = s\beta^{i_k}$ , where  $i_k$  is the smallest nonnegative integer satisfying (the sufficient decrease condition)

$$f(\mathbf{x}_k) - f(\mathbf{x}_k + s\beta^{i_k} \mathbf{d}_k) \ge -\alpha s\beta^{i_k} \nabla f(\mathbf{x}_k)^\top \mathbf{d}_k.$$

#### Lemma 6 (validity of the sufficient decrease condition)

Let f be a continuously differentiable function over  $\mathbb{R}^n$ . Suppose that  $\mathbf{0} \neq \mathbf{d} \in \mathbb{R}^n$  is a descent direction of f at  $\mathbf{x}$  and let  $\alpha \in (0, 1)$ . Then there exists  $\varepsilon > 0$  such that the inequality

$$f(\mathbf{x}) - f(\mathbf{x} + t\mathbf{d}) \ge -\alpha t \nabla f(\mathbf{x})^{\top} \mathbf{d}$$

holds for all  $t \in [0, \varepsilon]$ .

*Proof.* It follows from  $\mathbf{d}$  is a descent direction that

$$\lim_{t \to 0^+} \frac{(1-\alpha)t\nabla f(\mathbf{x})^\top \mathbf{d} + o(t\|\mathbf{d}\|)}{t} = (1-\alpha)\nabla f(\mathbf{x})^\top \mathbf{d} < 0.$$

Hence, there exists  $\varepsilon > 0$  such that for all  $t \in (0, \varepsilon]$  the inequality  $(1 - \alpha)t\nabla f(\mathbf{x})^{\top}\mathbf{d} + o(t\|\mathbf{d}\|) < 0$  holds. The statement follows from

$$f(\mathbf{x}) - f(\mathbf{x} + t\mathbf{d}) = -\alpha t \nabla f(\mathbf{x})^{\top} \mathbf{d} - (1 - \alpha) t \nabla f(\mathbf{x})^{\top} \mathbf{d} - o(t \|\mathbf{d}\|). \quad \Box$$

#### 4.2 The gradient method

• Set  $\mathbf{d}_k = -\nabla f(\mathbf{x}_k)$ , the steepest descent direction.

#### Lemma 7

Let f be a continuously differentiable function over  $\mathbb{R}^n$ , and let **x** be a nonstationary point  $(\nabla f(\mathbf{x}) \neq \mathbf{0})$ . Then we have

$$-\frac{\nabla f(\mathbf{x})}{\|\nabla f(\mathbf{x})\|} = \operatorname*{argmin}_{\mathbf{d} \in \mathbb{R}^n, \|\mathbf{d}\| = 1} \nabla f(\mathbf{x})^\top \mathbf{d}.$$

# Lemma 8 ("zig-zag")

Let  $\{\mathbf{x}_k\}$  be the sequence generated by the gradient method with exact line search for solving a problem of minimizing a continuously differentiable function f. Then for any k = 0, 1, 2, ...,

$$(\mathbf{x}_{k+2} - \mathbf{x}_{k+1})^\top (\mathbf{x}_{k+1} - \mathbf{x}_k) = 0.$$

• We assume that f is continuously differentiable and that  $\nabla f$  is Lipschitz continuous over  $\mathbb{R}^n$ : there exists L > 0 such that

$$\|\nabla f(\mathbf{x}) - \nabla f(\mathbf{y})\| \le L \|\mathbf{x} - \mathbf{y}\|, \quad \forall \ \mathbf{x}, \mathbf{y} \in \mathbb{R}^n.$$

• Notation:  $C_L^{1,1}(\mathbb{R}^n), C^{1,1}(\mathbb{R}^n), C_L^{1,1}(D), C^{1,1}(D)$ 

#### Theorem 9

Let f be a twice continuously differentiable function over  $\mathbb{R}^n$ . Then  $f \in C_L^{1,1}(\mathbb{R}^n) \Leftrightarrow \|\nabla^2 f(\mathbf{x})\| \leq L$  for any  $\mathbf{x} \in \mathbb{R}^n$ .

#### Lemma 10 (descent lemma)

Let  $D \subseteq \mathbb{R}^n$  and  $f \in C_L^{1,1}(D)$  for some L > 0. Then for any  $\mathbf{x}, \mathbf{y} \in D$  satisfying  $[\mathbf{x}, \mathbf{y}] \subseteq D$  it holds that

$$-\frac{L}{2} \|\mathbf{y} - \mathbf{x}\|^2 \le f(\mathbf{y}) - f(\mathbf{x}) - \nabla f(\mathbf{x})^\top (\mathbf{y} - \mathbf{x}) \le \frac{L}{2} \|\mathbf{y} - \mathbf{x}\|^2.$$

#### Lemma 11 (sufficient decrease lemma)

Suppose that  $f \in C_L^{1,1}(\mathbb{R}^n)$ . Then for any  $\mathbf{x} \in \mathbb{R}^n$  and t > 0, we have

$$f(\mathbf{x}) - f(\mathbf{x} - t\nabla f(\mathbf{x})) \ge t(1 - tL/2) \|\nabla f(\mathbf{x})\|^2.$$

#### Lemma 12 (sufficient decrease of the gradient method)

Let  $f \in C_L^{1,1}(\mathbb{R}^n)$ . Let  $\{\mathbf{x}_k\}$  be the sequence generated by the gradient method for solving  $\min_{\mathbf{x}\in\mathbb{R}^n} f(\mathbf{x})$  with one of the following stepsize strategies: constant stepsize  $\overline{t} \in (0, 2/L)$ , exact line search, backtracking procedure with parameters s > 0,  $\alpha \in (0, 1)$ , and  $\beta \in (0, 1)$ . Then

$$f(\mathbf{x}_k) - f(\mathbf{x}_{k+1}) \ge M \|\nabla f(\mathbf{x}_k)\|^2,$$

where

$$M = \begin{cases} \overline{t}(1 - \overline{t}L/2), & constant \ stepsize, \\ 1/(2L), & exact \ line \ search, \\ \alpha \min\{s, 2(1 - \alpha)\beta/L\}, & backtracking. \end{cases}$$

# Theorem 13 (convergence of the gradient method)

Let  $f \in C_L^{1,1}(\mathbb{R}^n)$ . Let  $\{\mathbf{x}_k\}$  be the sequence generated by the gradient method for solving

 $\min_{\mathbf{x}\in\mathbb{R}^n}f(\mathbf{x})$ 

with one of the following stepsize strategies: constant stepsize  $\overline{t} \in (0, 2/L)$ , exact line search, backtracking procedure with parameters s > 0,  $\alpha \in (0, 1)$ , and  $\beta \in (0, 1)$ . Assume that f is bounded below over  $\mathbb{R}^n$ , that is, there exists  $m \in \mathbb{R}$  such that  $f(\mathbf{x}) \ge m$  for all  $\mathbf{x} \in \mathbb{R}^n$ . Then we have the following:

(a) The sequence  $\{f(\mathbf{x}_k)\}$  is nonincreasing. In addition, for any  $k > 0, f(\mathbf{x}_{k+1}) < f(\mathbf{x}_k)$  unless  $\nabla f(\mathbf{x}_k) = 0$ .

(b) 
$$\nabla f(\mathbf{x}_k) \to \mathbf{0} \text{ as } k \to \infty.$$

(c) If 
$$\lim_{k \to \infty} f(\mathbf{x}_k) = f_{\star}$$
, then

$$\min_{k=0,1,\dots,n} \|\nabla f(\mathbf{x}_k)\| \le \sqrt{\frac{f(\mathbf{x}_0) - f_\star}{M(n+1)}}.$$

#### 4.3 The scaled gradient method

• Let  $\mathbf{S} \in \mathbb{R}^{n \times n}$  be nonsingular. Consider the equivalent problem

$$\min\{g(\mathbf{y}) \equiv f(\mathbf{S}\mathbf{y}) : \mathbf{y} \in \mathbb{R}^n\}.$$

We have  $\nabla g(\mathbf{y}) = \mathbf{S}^{\top} \nabla f(\mathbf{S}\mathbf{y}) = \mathbf{S}^{\top} \nabla f(\mathbf{x})$ . The gradient method takes the form

$$\mathbf{y}_{k+1} = \mathbf{y}_k - t_k \mathbf{S}^\top \nabla f(\mathbf{S} \mathbf{y}_k).$$

Multiplying by **S** from the left and using the notation  $\mathbf{x}_k = \mathbf{S}\mathbf{y}_k$ and  $\mathbf{D} = \mathbf{S}\mathbf{S}^\top$  yield

$$\mathbf{x}_{k+1} = \mathbf{x}_k - t_k \mathbf{D} \nabla f(\mathbf{x}_k).$$

The direction  $-\mathbf{D}\nabla f(\mathbf{x}_k)$  is a descent direction.

• It is often beneficial to choose the scaling matrix **D** differently at each iteration:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - t_k \mathbf{D}_k \nabla f(\mathbf{x}_k).$$

#### 4.4 Newton's method

• We assume that f is twice continuously differentiable. Given  $\mathbf{x}_k$ ,

$$\mathbf{x}_{k+1} = \mathbf{x}_k - (\nabla^2 f(\mathbf{x}_k))^{-1} \nabla f(\mathbf{x}_k).$$

If  $\nabla^2 f(\mathbf{x}_k)$  is positive definite, then  $\mathbf{x}_{k+1}$  is the minimizer of the following quadratic approximation of f around  $\mathbf{x}_k$ :

$$f(\mathbf{x}_k) + \nabla f(\mathbf{x}_k)^{\top} (\mathbf{x} - \mathbf{x}_k) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_k)^{\top} \nabla f(\mathbf{x}_k) (\mathbf{x} - \mathbf{x}_k).$$

• Damped Newton's method:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - t_k (\nabla^2 f(\mathbf{x}_k))^{-1} \nabla f(\mathbf{x}_k),$$

where  $t_k$  is the stepsize.

• Hybrid gradient-Newton method:

$$\mathbf{d}_{k} = \begin{cases} -(\nabla^{2} f(\mathbf{x}_{k}))^{-1} \nabla f(\mathbf{x}_{k}), & \text{if } \nabla^{2} f(\mathbf{x}_{k}) & \text{is pd,} \\ -\nabla f(\mathbf{x}_{k}), & \text{otherwise.} \end{cases}$$

Theorem 14 (quadratic local convergence of Newton's method)

Suppose  $f(\mathbf{x})$  is twice Lipschitz continuously differentiable with Lipschitz constant M > 0, i.e.,

$$\|\nabla^2 f(\mathbf{x}) - \nabla^2 f(\mathbf{y})\| \le M \|\mathbf{x} - \mathbf{y}\|.$$

Suppose that (the second-order sufficient conditions)

$$\nabla f(\mathbf{x}_{\star}) = \mathbf{0}, \quad and \quad \nabla^2 f(\mathbf{x}_{\star}) \succeq \gamma \mathbf{I} \quad for \ some \quad \gamma > 0,$$

which ensure that  $\mathbf{x}_{\star}$  is a local minimizer of  $f(\mathbf{x})$ . If

$$\|\mathbf{x}^0 - \mathbf{x}_\star\| \le \frac{\gamma}{2M},$$

then the sequence  $\{\mathbf{x}^k\}_0^\infty$  in Newton's method converges to  $\mathbf{x}_{\star}$  at a quadratic rate, with

$$\|\mathbf{x}^{k+1} - \mathbf{x}_{\star}\| \le \frac{M}{\gamma} \|\mathbf{x}^k - \mathbf{x}_{\star}\|^2, \quad k = 0, 1, 2, \dots.$$
